Contestant_Packet vs symposium_data

GRIDTECH benchmark: v5.5.1 (Contestant_Packet) compared with v6.0.1 "V2" (symposium_data, folder packet_v6.6.1)

> Same campus, demand, weather, grid schedule and stress events. V2 changes the **battery rules** and two catalog prices. The folder is named v6.6.1 but every file inside says v6.0.1; confirm the version number with the organizers.

What changed

Item	Contestant_Packet (v5.5.1)	symposium_data (v6.0.1 V2)
Battery charging	Only from contemporaneous clean contract generation	From any source: grid, offsite contracts or onsite gas. Behind the meter, no export or resale
Battery clean credit	Discharge minus charge counts as clean	Discharge is clean only in proportion to the clean share of that year's charging; grid-charged energy earns none
Battery maximum	12 MW (48 MWh)	53 MW (212 MWh), the most the 8-acre site allows
Battery CAPEX	$1,744/kW	$1,220/kW (−30%)
Wind contract price	$35/MWh	$45/MWh
Dispatch CSV	13 columns	14 columns: adds optional `battery_4h_clean_charge_mw` (omitted = all charging treated as clean)
Checker	Hash-locks the v5.5.1 data files	New hashes and clean-charge accounting; rejects clean charge above total charge
Rule documents	Clean-only battery rule	MODEL_RULES.md and Problem_Statement.md take precedence over the unchanged PDF

Unchanged

- Identical files: timeline, reference hourly profiles, stress events, response parameters, grid schedule, commissioning ramp.
- Solar, gas turbine, gas engine, fuel cell and nuclear prices; submission deadline and format.

Impact on the current app

- **Python backend:** still reads the old checker and data; its portfolios assumed clean-only charging.
- **Browser prototype:** its 384 pre-simulated plans used the old battery limit, wind price and charging rule, so results would differ.
- **Expected effect:** a larger, cheaper, grid-chargeable battery can shift cost-optimal portfolios and the cost/carbon trade-off.
